

Instructions for lab 3:

Write the assembly language program as shared.

On each line of code, add comments to indicate the addressing mode for the source and the destination

Debug the program and go into disassembly and register views.

In the disassembly view, the instructions are indicated to which the program counter points, followed by one or two fields depending on the addressing mode. Write the contents of memory and relevant registers before and after each instruction, indicating those values that change. Also compare the different fields in the instruction (all are move instructions and so it should be straightforward) and justify the opcode generated.

Draw the memory map of the MSP430G2553 and indicate the flash and RAM sections and their boundaries. Note where the assembler places the symbolic variables

The record must have each instruction expanded and mapped as shown in SLAU144K.

Relevant material has been included in PESU academy
